**Hydroxyethylamino sulphonamides useful as retroviral protease inhibitors****RELATED APPLICATION**

5        This application is a continuation in part  
application of co-owned and co-pending U.S. patent  
application Serial No. 08/204,827 filed March 2, 1994,  
which is a continuation in part application of co-owned  
and co-pending PCT/US93/07814, filed August 24, 1993,  
10      which is a continuation in part application of co-owned  
U.S. patent application Serial No. 07/934,984 filed  
August 25, 1992, now abandoned, each of which is  
incorporated herein by reference in its entirety.

15      **BACKGROUND OF THE INVENTION**

**1. Field of the Invention**

20      The present invention relates to retroviral  
protease inhibitors and, more particularly, relates to  
novel compounds and a composition and method for  
inhibiting retroviral proteases. This invention, in  
particular, relates to sulfonamide-containing  
hydroxyethylamine protease inhibitor compounds, a  
composition and method for inhibiting retroviral  
25      proteases such as human immunodeficiency virus (HIV)  
protease and for treating a retroviral infection, e.g.,  
an HIV infection. The subject invention also relates to  
processes for making such compounds as well as to  
intermediates useful in such processes.

30

**2. Related Art**

During the replication cycle of retroviruses,  
gag and gag-pol gene transcription products are translated  
as proteins. These proteins are subsequently processed by  
35      a virally encoded protease (or proteinase) to yield viral  
enzymes and structural proteins of the virus core. Most  
commonly, the gag precursor proteins are processed into

the core proteins and the pol precursor proteins are processed into the viral enzymes, e.g., reverse transcriptase and retroviral protease. It has been shown that correct processing of the precursor proteins by the 5 retroviral protease is necessary for assembly of infectious viroids. For example, it has been shown that frameshift mutations in the protease region of the pol gene of HIV prevents processing of the gag precursor protein. It has also been shown through site-directed 10 mutagenesis of an aspartic acid residue in the HIV protease active site that processing of the gag precursor protein is prevented. Thus, attempts have been made to inhibit viral replication by inhibiting the action of retroviral proteases.

15

Retroviral protease inhibition typically involves a transition-state mimetic whereby the retroviral protease is exposed to a mimetic compound which binds (typically in a reversible manner) to the enzyme in 20 competition with the gag and gag-pol proteins to thereby inhibit specific processing of structural proteins and the release of retroviral protease itself. In this manner, retroviral replication proteases can be effectively inhibited.

25

Several classes of compounds have been proposed, particularly for inhibition of proteases, such as for inhibition of HIV protease. Such compounds include hydroxyethylamine isosteres and reduced amide 30 isosteres. See, for example, EP 0 346 847; EP 0 342,541; Roberts et al, "Rational Design of Peptide-Based Proteinase Inhibitors," *Science*, 248, 358 (1990); and Erickson et al, "Design Activity, and 2.8Å Crystal 35 Structure of a C<sub>2</sub> Symmetric Inhibitor Complexed to HIV-1 Protease," *Science*, 249, 527 (1990).

Several classes of compounds are known to be useful as inhibitors of the proteolytic enzyme renin. See, for example, U.S. No. 4,599,198; U.K. 2,184,730; G.B. 2,209,752; EP O 264 795; G.B. 2,200,115 and U.S. SIR 5 H725. Of these, G.B. 2,200,115, GB 2,209,752, EP O 264,795, U.S. SIR H725 and U.S. 4,599,198 disclose urea-containing hydroxyethylamine renin inhibitors. EP 468 641 discloses renin inhibitors and intermediates for the preparation of the inhibitors, which include sulfonamide-containing hydroxyethylamine compounds, such as 3-(t-butoxycarbonyl)amino-cyclohexyl-1-(phenylsulfonyl)amino-2(5)-butanol. G.B. 2,200,115 also discloses sulfamoyl-containing hydroxyethylamine renin inhibitors, and EP 0264 795 discloses certain sulfonamide-containing 10 hydroxyethylamine renin inhibitors. However, it is known that, although renin and HIV proteases are both classified as aspartyl proteases, compounds which are effective renin inhibitors generally cannot be predicted 15 to be effective HIV protease inhibitors.

20

BRIEF DESCRIPTION OF THE INVENTION

The present invention is directed to virus 25 inhibiting compounds and compositions. More particularly, the present invention is directed to retroviral protease inhibiting compounds and compositions, to a method of inhibiting retroviral proteases, to processes for preparing the compounds and 30 to intermediates useful in such processes. The subject compounds are characterized as sulfonamide-containing hydroxyethylamine inhibitor compounds.

Procedures for preparing the compounds of Formula I are set forth below. It should be noted that 35 the general procedure is shown as it relates to

preparation of compounds having the specified stereochemistry, for example, wherein the absolute stereochemistry about the hydroxyl group is designated as (R). However, such procedures are generally applicable 5 to those compounds of opposite configuration, e.g., where the stereochemistry about the hydroxyl group is (S). In addition, the compounds having the (R) stereochemistry can be utilized to produce those having the (S) stereochemistry. For example, a compound having the (R) 10 stereochemistry can be inverted to the (S) stereochemistry using well-known methods.

An N-protected chloroketone derivative of an amino acid having the formula:

5

wherein P represents an amino protecting group, and R<sup>2</sup> is as defined above, is reduced to the corresponding alcohol utilizing an appropriate reducing agent. Suitable amino protecting groups are well known in the art and include 10 carbobenzoxy, t-butoxycarbonyl, and the like. A preferred amino protecting group is carbobenzoxy. A preferred N-protected chloroketone is N-benzyloxycarbonyl-L-phenylalanine chloromethyl ketone. A preferred reducing agent is sodium borohydride. The 15 reduction reaction is conducted at a temperature of from -10°C to about 25°C, preferably at about 0°C, in a suitable solvent system such as, for example, tetrahydrofuran, and the like. The N-protected chloroketones are commercially available, e.g., such as 20 from Bachem, Inc., Torrance, California. Alternatively, the chloroketones can be prepared by the procedure set forth in S. J. Fittkau, J. Prakt. Chem., 315, 1037 (1973), and subsequently N-protected utilizing procedures which are well known in the art.

25

The halo alcohol can be utilized directly, as described below, or, preferably, is then reacted, preferably at room temperature, with a suitable base in a suitable solvent system to produce an N-protected amino 30 epoxide of the formula:

wherein P and R<sup>2</sup> are as defined above. Suitable solvent systems for preparing the amino epoxide include ethanol, 5 methanol, isopropanol, tetrahydrofuran, dioxane, and the like including mixtures thereof. Suitable bases for producing the epoxide from the reduced chloroketone include potassium hydroxide, sodium hydroxide, potassium t-butoxide, DBU and the like. Alternatively, a protected amino epoxide can be prepared, such as in co-owned and co-pending PCT Patent Application Serial No. PCT/US93/04804 which is 15 incorporated herein by reference, starting with an L-amino acid which is reacted with a suitable amino-protecting group in a suitable solvent to produce an amino-protected L-amino acid ester of the formula:

20

wherein P<sup>3</sup> represents carboxyl-protecting group, e.g., methyl, ethyl, benzyl, tertiary-butyl and the like; R<sup>2</sup> is as defined above; and P<sup>1</sup> and P<sup>2</sup> independently are selected 25 from amine protecting groups, including but not limited to, arylalkyl, substituted arylalkyl, cycloalkenylalkyl and substituted cycloalkenylalkyl, allyl, substituted allyl, acyl, alkoxy carbonyl, aralkoxy carbonyl and silyl. Examples of arylalkyl include, but are not limited to benzyl, ortho-methylbenzyl, trityl and benzhydryl, which can be 30

optionally substituted with halogen, alkyl of C<sub>1</sub>-C<sub>8</sub>, alkoxy, hydroxy, nitro, alkylene, amino, alkylamino, acylamino and acyl, or their salts, such as phosphonium and ammonium salts. Examples of aryl groups include phenyl, 5 naphthalenyl, indanyl, anthracenyl, durenyl, 9-(9-phenylfluorenyl) and phenanthrenyl, cycloalkenylalkyl or substituted cycloalkenylalkyl radicals containing cycloalkyls of C<sub>6</sub>-C<sub>10</sub>. Additionally, the P<sup>1</sup> and/or P<sup>2</sup> protecting groups can form a heterocyclic ring with the nitrogen to which they 15 are attached, for example, 1,2-bis(methylene)benzene, phthalimidyl, succinimidyl, maleimidyl and the like and where these heterocyclic groups can further include adjoining aryl and cycloalkyl rings. In addition, the heterocyclic groups can be mono-, di- or tri-substituted, 20 e.g., nitrophthalimidyl. The term silyl refers to a silicon atom optionally substituted by one or more alkyl, aryl and aralkyl groups.

Suitable silyl protecting groups include, but are 25 not limited to, trimethylsilyl, triethylsilyl, tri-isopropylsilyl, tert-butyldimethylsilyl, dimethylphenylsilyl, 1,2-bis(dimethylsilyl)benzene, 1,2-bis(dimethylsilyl)ethane and diphenylmethylsilyl. Silylation of the amine functions to provide mono- or bis- 30 disilylamine can provide derivatives of the aminoalcohol, amino acid, amino acid esters and amino acid amide. In the case of amino acids, amino acid esters and amino acid amides, reduction of the carbonyl function provides the required mono- or bis-silyl aminoalcohol. Silylation of the 35 aminoalcohol can lead to the N,N,O-tri-silyl derivative. Removal of the silyl function from the silyl ether function is readily accomplished by treatment with, for example, a

metal hydroxide or ammonium flouride reagent, either as a discrete reaction step or in situ during the preparation of the amino aldehyde reagent. Suitable silylating agents are, for example, trimethylsilyl chloride, tert-butyl-  
5 dimethylsilyl chloride, phenyldimethylsilyl chloride, diphenylmethysilyl chloride or their combination products with imidazole or DMF. Methods for silylation of amines and removal of silyl protecting groups are well known to those skilled in the art. Methods of preparation of these amine  
10 derivatives from corresponding amino acids, amino acid amides or amino acid esters are also well known to those skilled in the art of organic chemistry including amino acid/amino acid ester or aminoalcohol chemistry.

15 Preferably P<sup>1</sup> and P<sup>2</sup> are independently selected from aralkyl and substituted aralkyl. More preferably, each of P<sup>1</sup> and P<sup>2</sup> is benzyl. As illustrated in the Examples below, P, P<sup>1</sup> and P<sup>2</sup> may serve as a nitrogen protecting group which is later removed in the  
20 preparation of compounds of this invention or may form a part of the final inhibitor structure. For example, benzoyl, benzyloxycarbonyl, t-butoxycarbonyl, pyridylmethoxycarbonyl, tetrahydrofuryloxycarbonyl, pyridylcarbonyl and the like can used to both protect a  
25 nitrogen from undergoing an undesired reaction and also be part of the structure of an active enzyme inhibitor.

The amino-protected L-amino acid ester is then reduced, to the corresponding alcohol. For example, the  
30 amino-protected L-amino acid ester can be reduced with diisobutylaluminum hydride at -78° C in a suitable solvent such as toluene. Preferred reducing agents include lithium aluminium hydride, lithium borohydride, sodium borohydride, borane, lithium tri-ter-  
35 buoxyaluminum hydride, borane/THF complex. Most preferably, the reducing agent is diisobutylaluminum hydride (DiBAL-H) in toluene. The resulting alcohol is

then converted, for example, by way of a Swern oxidation, to the corresponding aldehyde of the formula:

5

wherein P<sup>1</sup>, P<sup>2</sup> and R<sup>2</sup> are as defined above. Thus, a dichloromethane solution of the alcohol is added to a cooled (-75 to -68° C) solution of oxalyl chloride in dichloromethane and DMSO in dichloromethane and stirred 10 for 35 minutes.

Acceptable oxidizing reagents include, for example, sulfur trioxide-pyridine complex and DMSO, oxalyl chloride and DMSO, acetyl chloride or anhydride and DMSO, trifluoroacetyl chloride or anhydride and DMSO, methanesulfonyl chloride and DMSO or tetrahydro thiophene-S-oxide, toluenesulfonyl bromide and DMSO, trifluoromethanesulfonyl anhydride (triflic anhydride) and DMSO, phosphorus pentachloride and DMSO, 20 dimethylphosphoryl chloride and DMSO and isobutyl chloroformate and DMSO. The oxidation conditions reported by Reetz et al [Angew Chem., 99, p. 1186, (1987)], [Angew Chem. Int. Ed. Engl., 26, p. 1141, 1987] employed oxalyl chloride and DMSO at -78°C.

25

The preferred oxidation method described in this invention is sulfur trioxide pyridine complex, triethylamine and DMSO at room temperature. This system provides excellent yields of the desired chiral 30 protected amino aldehyde usable without the need for purification i.e., the need to purify kilograms of intermediates by chromatography is eliminated and large scale operations are made less hazardous. Reaction at room temperature also eliminated the need

for the use of low temperature reactor which makes the process more suitable for commercial production.

The reaction may be carried out under and  
5 inert atmosphere such as nitrogen or argon, or normal  
or dry air, under atmospheric pressure or in a sealed  
reaction vessel under positive pressure. Preferred is  
a nitrogen atmosphere. Alternative amine bases  
include, for example, tri-butyl amine, tri-isopropyl  
10 amine, N-methylpiperidine, N-methyl morpholine,  
azabicyclononane, diisopropylethylamine, 2,2,6,6-  
tetramethylpiperidine, N,N-dimethylaminopyridine, or  
mixtures of these bases. Triethylamine is a preferred  
base. Alternatives to pure DMSO as solvent include  
15 mixtures of DMSO with non-protic or halogenated  
solvents such as tetrahydrofuran, ethyl acetate,  
toluene, xylene, dichloromethane, ethylene dichloride  
and the like. Dipolar aprotic co-solvents include  
acetonitrile, dimethylformamide, dimethylacetamide,  
20 acetamide, tetramethyl urea and its cyclic analog,  
N-methylpyrrolidone, sulfolane and the like. Rather  
than N,N-dibenzylphenylalaninol as the aldehyde  
precursor, the phenylalaninol derivatives discussed  
above can be used to provide the corresponding  
25 N-monosubstituted [either P<sup>1</sup> or P<sup>2</sup> = H] or N,N-  
disubstituted aldehyde.

In addition, hydride reduction of an amide  
or ester derivative of the corresponding alkyl, benzyl  
30 or cycloalkenyl nitrogen protected phenylalanine,  
substituted phenylalanine or cycloalkyl analog of  
phenylalanine derivative can be carried out to provide  
the aldehydes. Hydride transfer is an additional  
method of aldehyde synthesis under conditions where  
35 aldehyde condensations are avoided, cf, Oppenauer  
Oxidation.

The aldehydes of this process can also be prepared by methods of reducing protected phenylalanine and phenylalanine analogs or their amide or ester derivatives by, e.g., sodium amalgam with HCl in ethanol or lithium or 5 sodium or potassium or calcium in ammonia. The reaction temperature may be from about -20°C to about 45°C, and preferably from about 5°C to about 25°C. Two additional methods of obtaining the nitrogen protected aldehyde include oxidation of the corresponding alcohol with bleach in the 10 presence of a catalytic amount of 2,2,6,6-tetramethyl-1-pyridyloxy free radical. In a second method, oxidation of the alcohol to the aldehyde is accomplished by a catalytic amount of tetrapropylammonium perruthenate in the presence of N-methylmorpholine-N-oxide.

15

Alternatively, an acid chloride derivative of a protected phenylalanine or phenylalanine derivative as disclosed above can be reduced with hydrogen and a catalyst such as Pd on barium carbonate or barium sulphate, with or 20 without an additional catalyst moderating agent such as sulfur or a thiol (Rosenmund Reduction).

The aldehyde resulting from the Swern oxidation is then reacted with a halomethylolithium reagent, which 25 reagent is generated *in situ* by reacting an alkyllithium or aryllithium compound with a dihalomethane represented by the formula  $X^1\text{CH}_2X^2$  wherein  $X^1$  and  $X^2$  independently represent I, Br or Cl. For example, a solution of the aldehyde and chloroiodomethane in THF is cooled to -78° C 30 and a solution of n-butyllithium in hexane is added. The resulting product is a mixture of diastereomers of the corresponding amino-protected epoxides of the formulas:

The diastereomers can be separated e.g., by chromatography, or, alternatively, once reacted in subsequent steps the diastereomeric products can be 5 separated. For compounds having the (S) stereochemistry, a D-amino acid can be utilized in place of the L-amino acid.

The addition of chloromethyl lithium or 10 bromomethyl lithium to a chiral amino aldehyde is highly diastereoselective. Preferably, the chloromethyl lithium or bromomethyl lithium is generated in-situ from the reaction of the dihalomethane and n-butyllithium. Acceptable methyleneating halomethanes include chloroiodomethane, 15 bromochloromethane, dibromomethane, diiodomethane, bromofluoromethane and the like. The sulfonate ester of the addition product of, for example, hydrogen bromide to formaldehyde is also a methyleneating agent. Tetrahydrofuran is the preferred solvent, however 20 alternative solvents such as toluene, dimethoxyethane, ethylene dichloride, methylene chloride can be used as pure solvents or as a mixture. Dipolar aprotic solvents such as acetonitrile, DMF, N-methylpyrrolidone are useful as solvents or as part of a solvent mixture. The reaction can 25 be carried out under an inert atmosphere such as nitrogen or argon. For n-butyl lithium can be substituted other organometallic reagents reagents such as methyl lithium, tert-butyl lithium, sec-butyl lithium, phenyllithium, phenyl sodium and the like. The reaction can be carried out at 30 temperatures of between about -80°C to 0°C but preferably between about -80°C to -20°C. The most preferred reaction temperatures are between -40°C to -15°C. Reagents can be added singly but multiple additions are preferred in certain conditions. The preferred pressure of the reaction is 35 atmospheric however a positive pressure is valuable under certain conditions such as a high humidity environment.

Alternative methods of conversion to the epoxides of this invention include substitution of other charged methylenation precursor species followed by their treatment with base to form the analogous anion. Examples of these 5 species include trimethylsulfoxonium tosylate or triflate, tetramethylammonium halide, methyl diphenylsulfoxonium halide wherein halide is chloride, bromide or iodide.

The conversion of the aldehydes of this invention 10 into their epoxide derivative can also be carried out in multiple steps. For example, the addition of the anion of thioanisole prepared from, for example, a butyl or aryl lithium reagent, to the protected aminoaldehyde, oxidation of the resulting protected aminosulfide alcohol with well 15 known oxidizing agents such as hydrogen peroxide, tert-butyl hypochlorite, bleach or sodium periodate to give a sulfoxide. Alkylation of the sulfoxide with, for example, methyl iodide or bromide, methyl tosylate, methyl mesylate, methyl triflate, ethyl bromide, isopropyl bromide, benzyl 20 chloride or the like, in the presence of an organic or inorganic base Alternatively, the protected aminosulfide alcohol can be alkylated with, for example, the alkylating agents above, to provide a sulfonium salts that are 25 subsequently converted into the subject epoxides with tert-amine or mineral bases.

The desired epoxides formed, using most preferred conditions, diastereoselectively in ratio amounts of at least about an 85:15 ratio (S:R). The product can be 30 purified by chromatography to give the diastereomerically and enantiomerically pure product but it is more conveniently used directly without purification to prepare retroviral protease inhibitors. The foregoing process is applicable to mixtures of optical isomers as well as 35 resolved compounds. If a particular optical isomer is desired, it can be selected by the choice of starting material, e.g., L-phenylalanine, D-phenylalanine, L-

phenylalaninol, D-phenylalaninol, D-hexahydrophenylalaninol and the like, or resolution can occur at intermediate or final steps. Chiral auxiliaries such as one or two equivalents of camphor sulfonic acid, citric acid, camphoric acid, 2-methoxyphenylacetic acid and the like can be used to form salts, esters or amides of the compounds of this invention. These compounds or derivatives can be crystallized or separated chromatographically using either a chiral or achiral column as is well known to those skilled 10 in the art.

The amino epoxide is then reacted, in a suitable solvent system, with an equal amount, or preferably an excess of, a desired amine of the formula 15  $R^3NH_2$ , wherein  $R^3$  is hydrogen or is as defined above. The reaction can be conducted over a wide range of temperatures, e.g., from about 10°C to about 100°C, but is preferably, but not necessarily, conducted at a temperature at which the solvent begins to reflux. 20 Suitable solvent systems include protic, non-protic and dipolar aprotic organic solvents such as, for example, those wherein the solvent is an alcohol, such as methanol, ethanol, isopropanol, and the like, ethers such as tetrahydrofuran, dioxane and the like, and toluene. 25  $N,N$ -dimethylformamide, dimethyl sulfoxide, and mixtures thereof. A preferred solvent is isopropanol. Exemplary amines corresponding to the formula  $R^3NH_2$  include benzyl amine, isobutylamine, n-butyl amine, isopentyl amine, isoamylamine, cyclohexanemethyl amine, naphthylene methyl 30 amine and the like. The resulting product is a 3-(N-protected amino)-3-( $R^2$ )-1-( $NHR^3$ )-propan-2-ol derivative (hereinafter referred to as an amino alcohol) can be represented by the formulas:

wherein P, P<sup>1</sup>, P<sup>2</sup>, R<sup>2</sup> and R<sup>3</sup> are as described above.

Alternatively, a haloalcohol can be utilized in place of  
5 the amino epoxide.

The amino alcohol defined above is then reacted  
in a suitable solvent with a sulfonyl chloride (R<sup>4</sup>SO<sub>2</sub>Cl)  
or sulfonyl anhydride in the presence of an acid  
10 scavenger. Suitable solvents in which the reaction can  
be conducted include methylene chloride, tetrahydrofuran.  
Suitable acid scavengers include triethylamine, pyridine.  
Preferred sulfonyl chlorides are methanesulfonyl chloride  
and benzenesulfonyl chloride. The resulting sulfonamide  
15 derivative can be represented, depending on the epoxide  
utilized by the formulas

20 wherein P, P<sup>1</sup>, P<sup>2</sup>, R<sup>2</sup>, R<sup>3</sup> and R<sup>4</sup> are as defined above.  
These intermediates are useful for preparing inhibitor  
compounds of the present invention and are also active  
inhibitors of retroviral proteases.

25 The sulfonyl halides of the formula R<sup>4</sup>SO<sub>2</sub>X can  
be prepared by the reaction of a suitable Grignard or  
alkyl lithium reagent with sulfonyl chloride, or sulfur  
dioxide followed by oxidation with a halogen, preferably  
chlorine. Also, thiols may be oxidized to sulfonyl  
30 chlorides using chlorine in the presence of water under  
carefully controlled conditions. Additionally, sulfonic

acids may be converted to sulfonyl halides using reagents such as  $\text{PCl}_5$ , and also to anhydrides using suitable dehydrating reagents. The sulfonic acids may in turn be prepared using procedures well known in the art. Such 5 sulfonic acids are also commercially available. In place of the sulfonyl halides, sulfinyl halides ( $\text{R}^4\text{SOX}$ ) or sulfenyl halides ( $\text{R}^4\text{SX}$ ) can be utilized to prepare compounds wherein the  $-\text{SO}_2-$  moiety is replaced by an  $-\text{SO}-$  or  $-\text{S}-$  moiety, respectively.

10

Following preparation of the sulfonamide derivative, the amino protecting group P or  $\text{P}^1$  and  $\text{P}^2$  amino protecting groups are removed under conditions which will not affect the remaining portion of the 15 molecule. These methods are well known in the art and include acid hydrolysis, hydrogenolysis and the like. A preferred method involves removal of the protecting group, e.g., removal of a carbobenzoxy group, by hydrogenolysis utilizing palladium on carbon in a suitable solvent system such as an alcohol, acetic acid, and the like or mixtures thereof. Where the protecting group is a t-butoxycarbonyl group, it can be removed utilizing an inorganic or organic acid, e.g., HCl or trifluoroacetic acid, in a suitable solvent system, e.g., 20 dioxane or methylene chloride. The resulting product is the amine salt derivative. Following neutralization of the salt, the amine is then reacted with an amino acid or corresponding derivative thereof represented by the formula  $(\text{PN}[\text{CR}^1'\text{ R}^1''])_t \text{CH}(\text{R}^1)\text{COOH}$  wherein t,  $\text{R}^1$ ,  $\text{R}^1'$  and 25  $\text{R}^1''$  are as defined above, to produce the antiviral 30 compounds of the present invention having the formula:

wherein t, P, R<sup>1</sup>, R<sup>1'</sup>, R<sup>2</sup>, R<sup>3</sup> and R<sup>4</sup> are as defined above. Preferred protecting groups in this instance are a benzyloxycarbonyl group or a t-butoxycarbonyl group. Where t is O and R<sup>1</sup> is alkyl, alkenyl, alkynyl, 5 cycloalkyl, -CH<sub>2</sub>SO<sub>2</sub>NH<sub>2</sub>, -CH<sub>2</sub>CO<sub>2</sub>CH<sub>3</sub>, -CO<sub>2</sub>CH<sub>3</sub>, -CONH<sub>2</sub>, -CH<sub>2</sub>C(O)NHCH<sub>3</sub>, -C(CH<sub>3</sub>)<sub>2</sub>(SH), -C(CH<sub>3</sub>)<sub>2</sub>(SCH<sub>3</sub>), -C(CH<sub>3</sub>)<sub>2</sub>[S(O)CH<sub>3</sub>], -C(CH<sub>3</sub>)<sub>2</sub>[S(O<sub>2</sub>)CH<sub>3</sub>], or an amino acid side chain, such materials are well known and many are commercially available from Sigma-Aldrich.

10

Where the amine is reacted with a derivative of an amino acid, e.g., when t=1, so that the amino acid is a β-amino acid, such β-amino acids can be prepared according to the procedure set forth in a co-owned, 15 copending patent application, U.S. Serial No. 07/853,561 or the following procedures.

Various methods have been proposed for the preparation of chiral β-amino acids. See, for example, 20 Chemistry and Biochemistry of Amino Acids, Vol. 4, Chapter 5, pp. 250-57, B. Weinstein, Ed., Dekker, N.Y. (1975). Furukawa et al, Chem. Pharm. Bull., 25, 1319 (1977), disclose asymmetric synthesis of β-amino acids by addition of chiral amines to carbon-carbon double bonds 25 having nitrile or ester groups in the α-position. However, optical purities of the β-amino acids thus produced range from 2 to 19%. Furukawa et al also report that optically active β-amino acids have been produced with optical purities ranging from 2 to 28% by reacting 30 chiral Schiff bases with Reformsky reagent. Terentev et al, Dohl. Ahad. Nauk SSR, 163, 674 (1965) disclose synthesis of β-aminobutyric acids involving addition of chiral amines to crotonic acid with optical purities ranging from 7-9%.

35

Brown et al, Tetrahedron Lett., Vol. 28, No. 19, pp 2179-2182 (1987), disclose a method of preparing

optically active disubstituted  $\beta$ -amino acids which involves asymmetric catalytic hydrogenation of N-substituted  $\alpha$ -(aminoalkyl) acrylates. In order to verify the stereochemistry of the product, Curtius rearrangement was effected on the monomethyl ester of optically enriched RR-anti-2,3-dimethyl-succinic acid and trapping of the incipient isocyanate derivative with tertiary alcohol, namely, t-butyl alcohol, to give the corresponding R-enriched  $\beta$ -amino acid. Ninomita et al., Tetrahedron Lett., Vol. 30, 2152-2157 (1975) studied the Curtius rearrangement utilizing benzoic acid, diphenylphosphoryl azide and triethylamine followed by treatment with various alcohols and found that t-butyl alcohol gives yields superior to benzyl alcohol, ethanol and phenol.

Utilization of a primary or secondary alcohol to trap an isocyanate derivative of a chiral mono-substituted succinate, and, in particular, in a Curtius rearrangement of a chiral mono-substituted succinate, to produce chiral  $\beta$ -amino acids significantly increases the overall yield. The resulting carbamate-protected  $\beta$ -amino esters are then saponified to produce the corresponding carbamate-protected  $\beta$ -amino acids which are then deprotected to produce  $\beta$ -amino acids possessing the same absolute configuration as naturally-occurring (L)-amino acids. The overall reaction sequence can be shown as follow:

wherein R<sup>1</sup>, R<sup>1'</sup>, R<sup>1''</sup>, and P<sup>3</sup> are as defined above and P<sup>4</sup>OH are preferably represents radicals derived from primary and secondary alcohols.

5 This process can also be used in the asymmetric synthesis of  $\beta$ -amino acids represented by the formula:

10 wherein R<sup>1</sup>, R<sup>1'</sup> and R<sup>1''</sup> are as defined above. Such compounds are formed by Curtius rearrangement of 2(R)-substituted succinates represented by the formula

15 wherein R<sup>1</sup>, R<sup>1'</sup>, R<sup>1''</sup> and P<sup>3</sup> are as defined above, to afford the isocyanate derivative:

20 Using 2(S)-substituted succinates, 2(S)-substituted  $\beta$ -amino acids can also be prepared stereospecifically.

Curtius rearrangement involves pyrolysis of  
 25 acyol azides ( $\text{R}-\overset{\text{O}}{\underset{\parallel}{\text{C}}}-\text{N}=\text{N}=\text{N}$ ) to yield isocyanates ( $\text{R}-\text{N}=\text{C}=\text{O}$ ) which can be subsequently hydrolyzed to give amines. See March, Advanced Organic Chemistry, p. 1005, 2nd ed (1977). As a general rule, Curtius rearrangement is a concerted reaction and therefore proceeds with retention  
 30 of configuration of the starting materials.

- Determination of specific reaction conditions for effecting Curtius rearrangements of various succinates is within the skill of one in the art familiar with such reactions. In the method of the present invention,
- 5 Curtius rearrangement to afford the desired isocyante is preferably effected by treating a 2-substituted succinate with one equivalent of diphenoxypyrophosphoryl azide  $(PhO)_2PON_3$  and triethylamine to form the acyl azide followed by heating in an inert solvent, such as in warm
- 10 toluene, preferably at about 80°C for about three hours, to afford the isocyante derivative.

Suitable primary and secondary alcohols include those represented by the formula  $P^4OH$  where  $P^4$  represents substituted and unsubstituted alkyl, cycloalkyl, aralkyl and aryl radicals, as well as suitable equivalents such as, for example, silyl radicals. Preferably, the primary and secondary alcohols are those wherein  $P^4$  represents substituted and unsubstituted, straight chain as well as branched chain, alkyl radicals having from 1 to about 12 carbon atoms, substituted and unsubstituted cycloalkyl radicals having from 4 to about 7 carbon atoms, and substituted and unsubstituted aryl, alkaryl and aralkyl radicals.

20 Examples of such suitable alcohols include benzyl alcohol, isopropyl alcohol, 4-methoxybenzyl alcohol, 2-trimethylsilylethanol, fluorenyl methanol and benzhydrol. Preferred alcohols are benzyl alcohol and 4-methoxybenzyl alcohol. Other primary and secondary alcohols suitable

25 for use in the practice of the present invention will be readily apparent to those skilled in the art.

The ester derivative is then saponified by any one of numerous well-known procedures, such as by

30 treatment with aqueous lithium hydroxide/THF (tetrahydrofuran), preferably for three hours at 0°C. The resultant product is the corresponding carbamate-

protected  $\beta$ -amino acids. These are subsequently deprotected by any one of several well-known procedures, such as by acid catalyzed hydrolysis or by hydrogenolysis, to produce the corresponding deprotected  $\beta$ -amino acids. Alternatively, the carbamate-protected  $\beta$ -amino acid can be coupled to the amine

followed by deprotection and incorporation of R and R'.

10

The N-protecting group can be subsequently removed, if desired, utilizing the procedures described above, and then reacted with a carboxylate represented by

the formula  $\text{R}-\text{C}-\text{L}$ , wherein R is as defined above and 15 L is an appropriate leaving group such as a halide. Preferably, where R<sup>1</sup> is a side chain of a naturally occurring  $\alpha$ -amino acid, R is a 2-quinoline carbonyl group derived from N-hydroxysuccinimide-2-quinoline carboxylate, i.e., L is hydroxy succinimide. A solution 20 of the free amine (or amine acetate salt) and about 1.0 equivalent of the carboxylate are mixed in an appropriate solvent system and optionally treated with up to five equivalents of a base such as, for example, N-methylmorpholine, at about room temperature. Appropriate 25 solvent systems include tetrahydrofuran, methylene chloride or N,N-dimethyl formamide, and the like, including mixtures thereof.

Alternatively, the protected amino alcohol from 30 the epoxide opening can be further protected at the newly introduced amino group with a protecting group P' which is not removed when the first protecting P is removed. One skilled in the art can choose appropriate combinations of P

and P'. One suitable choice is when P is Cbz and P' is Boc. The resulting compound represented by the formula:

5

can be carried through the remainder of the synthesis to provide a compound of the formula:

10

and the new protecting group P' is selectively removed, and following deprotection, the resulting amine reacted to form the sulfonamide derivative as described above. This selective deprotection and conversion to the sulfonamide 15 can be accomplished at either the end of the synthesis or at any appropriate intermediate step if desired.

The thiocarbonyl compounds of this invention are really prepared by methods well known to those 20 skilled in the art, for example, by treatment of a carbonyl compound with Lawesson's reagent (2,4-bis(4-methoxyphenyl)-1,3-dithia-2,4-diphosphetane-2,4-disulfide) which is an article of commerce. Phosphorus pentasulfide may also be used or one can treat an amine 25 of this invention with a pre-formed thiocarbonyl reagent such as thiocarbonylchlorid in the presence of base.

In place of the sulfonyl halides, sulfinyl halides (RSOC<sub>1</sub>) and sulfenyl halides (RSCL) can be 30 utilized to prepare compounds wherein the -SO<sub>2</sub>- moiety is replaced by -SO- or -S-, respectively.

It is contemplated that for preparing compounds of the Formulas having R<sup>6</sup>, the compounds can be prepared following the procedure set forth above and, prior to 5 coupling the sulfonamide derivative or analog thereof, e.g. coupling to the amino acid PNH(CH<sub>2</sub>)<sub>t</sub>CH(R<sup>1</sup>)COOH, carried through a procedure referred to in the art as reductive amination. Thus, a sodium cyanoborohydride and an appropriate aldehyde or ketone can be reacted with the 10 sulfonamide derivative compound or appropriate analog at room temperature in order to reductively aminate any of the compounds of Formulas I-IV. It is also contemplated that where R<sup>3</sup> of the amino alcohol intermediate is hydrogen, the inhibitor compounds of the present 15 invention wherein R<sup>3</sup> is alkyl, or other substituents wherein the α-C contains at least one hydrogen, can be prepared through reductive amination of the final product of the reaction between the amino alcohol and the amine or at any other stage of the synthesis for preparing the 20 inhibitor compounds.

Contemplated equivalents of the general formulas set forth above for the antiviral compounds and derivatives as well as the intermediates are compounds 25 otherwise corresponding thereto and having the same general properties, such as tautomers thereof as well as compounds, wherein one or more of the various R groups are simple variations of the substituents as defined therein, e.g., wherein R is a higher alkyl group than 30 that indicated. In addition, where a substituent is designated as, or can be, a hydrogen, the exact chemical nature of a substituent which is other than hydrogen at that position, e.g., a hydrocarbyl radical or a halogen, hydroxy, amino and the like functional group, is not 35 critical so long as it does not adversely affect the overall activity and/or synthesis procedure.

The chemical reactions described above are generally disclosed in terms of their broadest application to the preparation of the compounds of this invention. Occasionally, the reactions may not be applicable as described to each compound included within the disclosed scope. The compounds for which this occurs will be readily recognized by those skilled in the art. In all such cases, either the reactions can be successfully performed by conventional modifications known to those skilled in the art, e.g., by appropriate protection of interfering groups, by changing to alternative conventional reagents, by routine modification of reaction conditions, and the like, or other reactions disclosed herein or otherwise conventional, will be applicable to the preparation of the corresponding compounds of this invention. In all preparative methods, all starting materials are known or readily preparable from known starting materials.

Without further elaboration, it is believed that one skilled in the art can, using the preceding description, utilize the present invention to its fullest extent. The following preferred specific embodiments are, therefore, to be construed as merely illustrative, and not limitative of the remainder of the disclosure in any way whatsoever.

All reagents were used as received without purification. All proton and carbon NMR spectra were obtained on either a Varian VXR-300 or VXR-400 nuclear magnetic resonance spectrometer.

The following Examples 1 through 9 illustrate preparation of intermediates. These intermediates are useful in preparing the inhibitor compounds of the

present invention as illustrated in Examples 10-16. In addition, the intermediates of Examples 2-6 are also retroviral protease inhibitors and inhibit, in particular, HIV protease.

Example 1A

10 Preparation of N[3(S)-benzyloxycarbonylamino-2(R)-hydroxy-4-phenylbutyl]-N-isoamylamine

Part A:

To a solution of 75.0g (0.226 mol) of  
15 N-benzyloxycarbonyl-L-phenylalanine chloromethyl ketone  
in a mixture of 807 mL of methanol and 807 mL of  
tetrahydrofuran at -2°C, was added 13.17g (0.348 mol,  
1.54 equiv.) of solid sodium borohydride over one hundred  
minutes. The solvents were removed under reduced  
20 pressure at 40°C and the residue dissolved in ethyl  
acetate (approx. 1L). The solution was washed  
sequentially with 1M potassium hydrogen sulfate,  
saturated sodium bicarbonate and then saturated sodium  
chloride solutions. After drying over anhydrous  
25 magnesium sulfate and filtering, the solution was removed  
under reduced pressure. To the resulting oil was added  
hexane (approx. 1L) and the mixture warmed to 60°C with  
swirling. After cooling to room temperature, the solids  
were collected and washed with 2L of hexane. The  
30 resulting solid was recrystallized from hot ethyl acetate  
and hexane to afford 32.3g (43% yield) of

N-benzyloxycarbonyl-3(S)-amino-1-chloro-4-phenyl-2(S)-butanol, mp 150-151°C and M<sup>+</sup>Li<sup>+</sup> = 340.

Part B:

5 To a solution of 6.52g (0.116 mol, 1.2 equiv.) of potassium hydroxide in 968 mL of absolute ethanol at room temperature, was added 32.3g (0.097 mol) of N-CBZ-3(S)-amino-1-chloro-4-phenyl-2(S)-butanol. After stirring for fifteen minutes, the solvent was removed  
10 under reduced pressure and the solids dissolved in methylene chloride. After washing with water, drying over magnesium sulfate, filtering and stripping, one obtains 27.9g of a white solid. Recrystallization from hot ethyl acetate and hexane afforded 22.3g (77% yield)

The solution was cooled to room temperature, concentrated  
25 in vacuo and then poured into 100 mL of stirring hexane whereupon the product crystallized from solution. The product was isolated by filtration and air dried to give 1.18g, 95% of N-[(3(S)-phenylmethylcarbamoyl)amino-2(R)-hydroxy-4-phenylbutyl]N-[(3-methylbutyl)]amine mp 108.0-109.5°C, M<sup>+</sup> m/z = 371.

Example 1B

5 Preparation of N,N-dibenzyl-3(S)-amino-1,2-(S)-epoxy-4-phenylbutane

Step A:

A solution of L-phenylalanine (50.0 g, 0.302 mol),  
10 sodium hydroxide (24.2 g, 0.605 mol) and potassium  
carbonate (83.6 g, 0.605 mol) in water (500 ml) was  
heated to 97°C. Benzyl bromide (108.5 ml, 0.912 mol) was  
then slowly added (addition time ~25 min). The mixture  
was then stirred at 97°C for 30 minutes. The solution  
15 was cooled to room temperature and extracted with toluene  
(2 x 250 ml). The combined organic layers were then  
washed with water, brine, dried over magnesium sulfate,  
filtered and concentrated to give an oil product. The  
crude product was then used in the next step without  
20 purification.

Step B:

The crude benzylated product of the above step was  
dissolved in toluene (750 ml) and cooled to -55°C. A 1.5  
25 M solution of DIBAL-H in toluene (443.9 ml, 0.666 mol)  
was then added at a rate to maintain the temperature  
between -55° to -50°C (addition time - 1 hour). The  
mixture was stirred for 20 minutes at -55°C. The  
reaction was quenched at -55°C by the slow addition of

methanol (37 ml). The cold solution was then poured into cold (5°C) 1.5 N HCl solution (1.8 L). The precipitated solid (approx. 138 g) was filtered off and washed with toluene. The solid material was suspended in a mixture 5 of toluene (400 ml) and water (100 ml). The mixture was cooled to 5°C, treated with 2.5 N NaOH (186 ml) and then stirred at room temperature until the solid was dissolved. The toluene layer was separated from the aqueous phase and washed with water and brine, dried over 10 magnesium sulfate, filtered and concentrated to a volume of 75 ml (89 g). Ethyl acetate (25 ml) and hexane (25 ml) were then added to the residue upon which the alcohol product began to crystallize. After 30 min., an additional 50 ml hexane was added to promote further 15 crystallization. The solid was filtered off and washed with 50 ml hexane to give approximately 35 g of material. A second crop of material could be isolated by refiltering the mother liquor. The solids were combined and recrystallized from ethyl acetate (20 ml) and hexane 20 (30 ml) to give, in 2 crops, approximately 40 g (40% from L-phenylalanine) of analytically pure alcohol product. The mother liquors were combined and concentrated (34 g). The residue was treated with ethyl acetate and hexane which provided an additional 7 g (~7% yield) of slightly 25 impure solid product. Further optimization in the recovery from the mother liquor is probable.

Alternatively, the alcohol was prepared from L-phenylalaninol. L-phenylalaninol (176.6 g, 1.168 mol) 30 was added to a stirred solution of potassium carbonate (484.6 g, 3.506 mol) in 710 mL of water. The mixture was heated to 65°C under a nitrogen atmosphere. A solution of benzyl bromide (400 g, 2.339 mol) in 3A ethanol (305 mL) was added at a rate that maintained 35 the temperature between 60-68°C. The biphasic solution was stirred at 65°C for 55 min and then allowed to cool to 10°C with vigorous stirring. The

oily product solidified into small granules. The product was diluted with 2.0 L of tap water and stirred for 5 minutes to dissolve the inorganic by products. The product was isolated by filtration  
5 under reduced pressure and washed with water until the pH is 7. The crude product obtained was air dried overnite to give a semi-dry solid (407 g) which was recrystallized from 1.1 L of ethyl acetate/heptane (1:10 by volume). The product was isolated by  
10 filtration (at -8°C), washed with 1.6 L of cold (-10°C) ethyl acetate/heptane (1:10 by volume) and air-dried to give 339 g (88% yield) of BS-2-[Bis(phenylmethyl)amino]benzene-propanol, mp 71.5-  
15 73.0°C. More product can be obtained from the mother liquor if necessary. The other analytical characterization was identical to compound prepared as described above.

Step C:

20 A solution of oxalyl chloride (8.4 ml, 0.096 mol) in dichloromethane (240 ml) was cooled to -74°C. A solution of DMSO (12.0 ml, 0.155 mol) in dichloromethane (50 ml) was then slowly added at a rate to maintain the temperature at -74°C (addition time ~1.25 hr). The  
25 mixture was stirred for 5 min. followed by addition of a solution of the alcohol (0.074 mol) in 100 ml of dichloromethane (addition time ~20 min., temp. -75°C to -68°C). The solution was stirred at -78°C for 35 minutes. Triethylamine (41.2 ml, 0.295 mol) was then  
30 added over 10 min. (temp. -78° to -68°C) upon which the ammonium salt precipitated. The cold mixture was stirred for 30 min. and then water (225 ml) was added. The dichloromethane layer was separated from the aqueous phase and washed with water, brine, dried over magnesium  
35 sulfate, filtered and concentrated. The residue was diluted with ethyl acetate and hexane and then filtered to further remove the ammonium salt. The filtrate was

concentrated to give the desired aldehyde product. The aldehyde was carried on to the next step without purification.

5        Temperatures higher than -70°C have been reported in the literature for the Swern oxidation. Other Swern modifications and alternatives to the Swern oxidations are also possible.

10      Alternatively, the aldehyde was prepared as follows. (200 g, 0.604 mol) was dissolved in triethylamine (300 mL, 2.15 mol). The mixture was cooled to 12°C and a solution of sulfur trioxide/pyridine complex (380 g, 2.39 mol) in DMSO (1.6 L) was added at a rate to maintain the 15 temperature between 8-17°C (addition time - 1.0 h). The solution was stirred at ambient temperature under a nitrogen atmosphere for 1.5 hour at which time the reaction was complete by TLC analysis (33% ethyl acetate/hexane, silica gel). The reaction mixture was 20 cooled with ice water and quenched with 1.6 L of cold water (10-15°C) over 45 minutes. The resultant solution was extracted with ethyl acetate (2.0 L), washed with 5% citric acid (2.0 L), and brine (2.2 L), dried over MgSO<sub>4</sub> (280 g) and filtered. The solvent was removed on a 25 rotary evaporator at 35-40°C and then dried under vacuum to give 198.8 g of αS-[Bis-(phenylmethyl)amino]-benzenepropanaldehyde as a pale yellow oil (99.9%). The crude product obtained was pure enough to be used directly in the next step without purification. The 30 analytical data of the compound were consistent with the published literature. Step D:

A solution of  $\alpha$ -S-[Bis(phenylmethyl)amino] benzene-propanaldehyde (191.7 g, 0.58 mol) and chloroiodomethane (56.4 mL, 0.77 mol) in tetrahydrofuran (1.8 L) was cooled to -30 to -35°C (colder temperature such as -70°C also worked well but warmer temperatures are more readily achieved in large scale operations) in a stainless steel reactor under a nitrogen atmosphere. A solution of n-butyllithium in hexane (1.6 M, 365 mL, 0.58 mol) was then added at a rate that maintained the temperature below -25°C. After addition the mixture was stirred at -30 to -35°C for 10 minutes. More additions of reagents were carried out in the following manner: (1) additional chloroiodomethane (17 mL) was added, followed by n-butyllithium (110 mL) at < -25°C. After addition the mixture was stirred at -30 to -35°C for 10 minutes. This was repeated once. (2) Additional chloroiodomethane (8.5 mL, 0.11 mol) was added, followed by n-butyllithium (55 mL, 0.088 mol) at <-25°C. After addition, the mixture was stirred at -30 to -35°C for 10 minutes. This was repeated 5 times. (3) Additional chloroiodomethane (8.5 mL, 0.11 mol) was added, followed by n-butyllithium (37 mL, 0.059 mol) at <-25°C. After addition, the mixture was stirred at -30 to -35°C for 10 minutes. This was repeated once. The external cooling was stopped and the mixture warmed to ambient temp. over 4 to 16 hours when TLC (silica gel, 20% ethyl acetate/hexane) indicated that the reaction was completed. The

reaction mixture was cooled to 10°C and quenched with 1452 g of 16% ammonium chloride solution (prepared by dissolving 232 g of ammonium chloride in 1220 mL of water), keeping the temperature below 23°C. The 5 mixture was stirred for 10 minutes and the organic and aqueous layers were separated. The aqueous phase was extracted with ethyl acetate (2x 500 mL). The ethyl acetate layer was combined with the tetrahydrofuran layer. The combined solution was dried over magnesium 10 sulfate (220 g), filtered and concentrated on a rotary evaporator at 65°C. The brown oil residue was dried at 70°C in vacuo (0.8 bar) for 1 h to give 222.8 g of crude material. (The crude product weight was >100%. Due to the relative instability of the product on 15 silica gel, the crude product is usually used directly in the next step without purification). The diastereomeric ratio of the crude mixture was determined by proton NMR: (2S)/(2R): 86:14. The minor and major epoxide diastereomers were characterized in 20 this mixture by tlc analysis (silica gel, 10% ethyl acetate/hexane), R<sub>f</sub> = 0.29 & 0.32, respectively. An analytical sample of each of the diastereomers was obtained by purification on silica-gel chromatography (3% ethyl acetate/hexane) and characterized as 25 follows:

Alternatively, a solution of the crude aldehyde 0.074 mol and chloroiodomethane (7.0 ml, 0.096 mol) in tetrahydrofuran (285 ml) was cooled to -78°C, under a nitrogen atmosphere. A 1.6 M solution of n-butyllithium in hexane (25 ml, 0.040 mol) was then added at a rate to maintain the temperature at -75°C (addition time - 15 min.). After the first addition, additional chloroiodomethane (1.6 ml, 0.022 mol) was added again, followed by n-butyllithium (23 ml, 0.037 mol), keeping the temperature at -75°C. The mixture was stirred for 15 min. Each of the reagents, chloroiodomethane (0.70 ml, 0.010 mol) and n-butyllithium (5 ml, 0.008 mol) were added 4 more times over 45 min. at -75°C. The cooling bath was then removed and the solution warmed to 22°C over 1.5 hr. The mixture was poured into 300 ml of saturated aq. ammonium chloride solution. The tetrahydrofuran layer was separated. The aqueous phase was extracted with ethyl acetate (1 x 300 ml). The combined organic layers were washed with brine, dried over magnesium sulfate, filtered and concentrated to give a brown oil (27.4 g). The product could be used in the next step without purification. The desired diastereomer can be

purified by recrystallization at a subsequent step.  
The product could also be purified by chromatography.

The external cooling was stopped and the mixture  
30 warmed to ambient temp. over 4 to 16 hours when TLC  
(silica gel, 20% ethyl acetate/hexane) indicated that

A one-necked 100 mL round-bottomed flask (magnetic stirring) was charged with 1.0 gram (6.6 mM) 3-amino-2-methylbenzoic acid. A warm mixture of 2.3 mL conc. sulfuric acid in 4.3 mL water was added to the flask, the resulting slurry was cooled below 15°C in an ice bath, and 6.6 grams of ice was added. The reaction mixture was treated via subsurface addition with a solution of 0.6 gram (8.6 mM) sodium nitrite in 6.6 mL ice water with the reaction temperature maintained at 0-5°C during the addition. After stirring at 0-5°C for 30 min., a few crystals of urea were added to decompose the excess nitrite. The reaction mixture was then poured into a room temperature solution of 23.8 grams (102.3 mM) copper (II) nitrate hemipentahydrate in 200 mL water. With vigorous stirring, the reaction mixture was treated with 0.9 gram (6.0 mM) copper (I) oxide. The reaction mixture foamed and changed from turquoise blue to dark green in color. Reaction was left stirring for 30 min. The reaction mixture was extracted with diethyl ether (3X), and the organic extracts were combined. The organic extracts were concentrated to approximately one-fourth the original volume, then extracted with 25 mL 1N sodium

hydroxide solution. The layers were separated, and the dark-red aqueous layer was acidified to pH=2 using 1N hydrochloric acid solution. The acidified aqueous layer was then extracted with diethyl ether (3X), and the ether extracts were combined, dried ( $MgSO_4$ ), and concentrated to yield a reddish-colored oil. Purification by flash chromatography on silica gel using a gradient of 0-7% methanol/methylene chloride afforded 0.39 grams (36%) of a yellow solid.

- 10 To a solution of 187 mg (1.23 mmol) of 3-hydroxy-2-methylbenzoic acid and 217 mg (1.61 mmol) of N-hydroxybenzotriazole in 6 mL of anhydrous N,N-dimethylformamide at 0°C, was added 236 mg (1.23 mmol) of EDC. After 20 minutes of activation at 0°C and 1 hour at room temperature, 450 mg (1.07 mmol) of 2R-hydroxy-3-  
15 [[(1,3-benzodioxol-5-yl)sulfonyl](2-methylpropyl)amino]-1S-(phenylmethyl)propylamine was added. After 15 hours at room temperature, ethyl acetate was added, washed with 5% citric acid, saturated sodium bicarbonate, brine, dried, filtered and concentrated to afford 650 mg of crude material. This was chromatographed on silica gel using 0-25% ethyl acetate/methylene chloride as eluent to afford 390 mg of pure benzamide, N-[2R-hydroxy-3-[[[(1,3-benzodioxol-5-yl)sulfonyl](2-methylpropyl)amino]-1S-(phenylmethyl)propyl]-3-hydroxy-2-methyl, m/e=561(M+Li).
